# Economic Value of Nuclear Power in Future Energy Systems

Required subsidy in various scenarios regarding future renewable generation, electricity demand and fossil fuel generation

Background				

## Background

To reduce carbon emissions, we can

- **1** reduce the use of energy
- 2 increase use of electricity
- **3** replace fossil generated electricity by non-carbon energy such as renewables and nuclear

Governments are promoting renewable power but are increasingly considering nuclear as mitigation measure. The Dutch government has asked market parties to build two nuclear power plants

Research questions			

#### Research questions

In an electricity system with high shares of renewable generation

- **I** To what extent does nuclear power require subsidy in comparison to other non-carbon sources?
- 2 How effective is nuclear power in providing flexibility to zero carbon electricity systems in comparison to hydrogen production, storage and usage?

Method	Sensitivity analysis	Conclusions
000000000 00000 0

#### Power market model

Short-term partial equilibrium model Electricity:

- Supply: produce electricity when price is higher than marginal cost
  - Gas-fired power plants
  - Nuclear power plants
  - Solar PV, onshore wind, offshore wind
  - International trader
  - Storage operator (in scenario with zero-carbon system)
- Demand: aggregated
- Result: electricity prices, production

Green certificates

#### Assumptions, costs

Cost	Unit	Nuclear	Te Solar	chnology Wind (on- shore)	Wind (off- shore)
Construction cost	€/kW installed	4230	750*	1125*	$2160^{*}$
Fixed O&M cost	€/kW installed	90	32.4	55.8	157.5
Variable O&M cost	€/MWh produced	1.35	-	-	-
Fuel cost	€/MWh produced	9.00	-	-	-
Cost of waste	€/MWh produced	2.07	-	-	-
Decommissioning cost	% of construction cost	$15^{*}$	$5^*$	$5^{*}$	$5^{*}$

#### Notes:

All values come from OECD-NEA (2019), page 94, except the values indicated with an \*, which come from IEA-NEA (2020). We assume an exchange rate of 0.90 Euro/USD.

The assumed values for the renewable energy technologies are relatively low compared to what is stated by Frauenhofer ISE (2021). That report states that the fixed costs per MW installed capacity are between 530 and 1600 for solar PV, between 1400 and 2000 for onshore wind, and between 3000 and 4000 for offshore wind. The costs of Solar PV very much depend on the type of installation: large utility scale PV installations are about 50 percent less expensive than small rooftop installations.

# Scenarios: regarding renewable capacities and electricity demand

Renewable capacities

High Renewables: renewable target in 2050

Electricity demand

Medium Increase, High Increase: electrification

Gas-fired power plants:

- capacity is adjusted accordingly to remain the same return rate per unit of installed capacity.
- sensitivity: scenario without gas-fired power plants

## Conclusions

- In current power system, building an nuclear power plant requires subsidies
- In a scenario with already high amounts of renewables, building an nuclear power plant requires less subsidies than building even more renewables (because of impact on capture prices)
- 3 Nuclear power plants benefit more from high gas and carbon prices than renewables
- It is more efficient to build a nuclear power plant to provide flexibility than to use hydrogen for that purpose in zero-carbon electricity system
